

WRITERS

Route handler
inline validation, then
durable mutation

Background loop
a claimed job, writing
the same tables

Apply + promoter
the release path

AUTHORITATIVE OWNERS

Relational metadata
OWNS the control plane:
registries, jobs, approvals,
runs, deployments, verdicts,
audit log, effect ledger,
and the file inventory
NOT file bytes.
NOT prompt versions.

Object storage
OWNS file bytes: uploads,
artifacts, exports, archives
NOT the inventory.

MLflow
OWNS prompt registry versions,
aliases, traces, assessments
NOT workflow or tool metadata.

RELATIONAL DOMAINS

Core governance
verification items, refinement jobs, approvals

Registries
prompt, tool, skill, MCP, workflow versions

Knowledge & quality
bases, chunks, eval runs, judges, verdicts

Platform
projects, files, secrets, sessions, incidents

The two dashed crossings are dual-write boundaries
A database-resident mutation and its audit_record call share ONE SQL transaction, so control-plane state and its audit row cannot diverge.
Object-storage writes and external registry effects cannot join that transaction: they settle by idempotent retry, not by atomicity. Importing the audit helper does not prove every mutation in a module is audited.

Reader path
A read resolves relational metadata first, then dereferences bytes or registry versions. The inventory is never rebuilt from a bucket listing.

71 tables carry the control plane. Solid edges are transactional; the two dashed edges are the honest limit.
